Glacial Dispersion Models

- ◆ Dilution (or enrichment) of geochemical or mineralogical till concentrations at a geological contact have historically been described using two types of quantitative dispersion models:
 - ***Exponential Dispersion***
basal (lodgement) till
 - ***Linear Dispersion***
overlying (ablation/melt-out) till

Glacial Dispersion Models

Glacial Dispersion Models

% Metasediment Clasts in Ablation Till

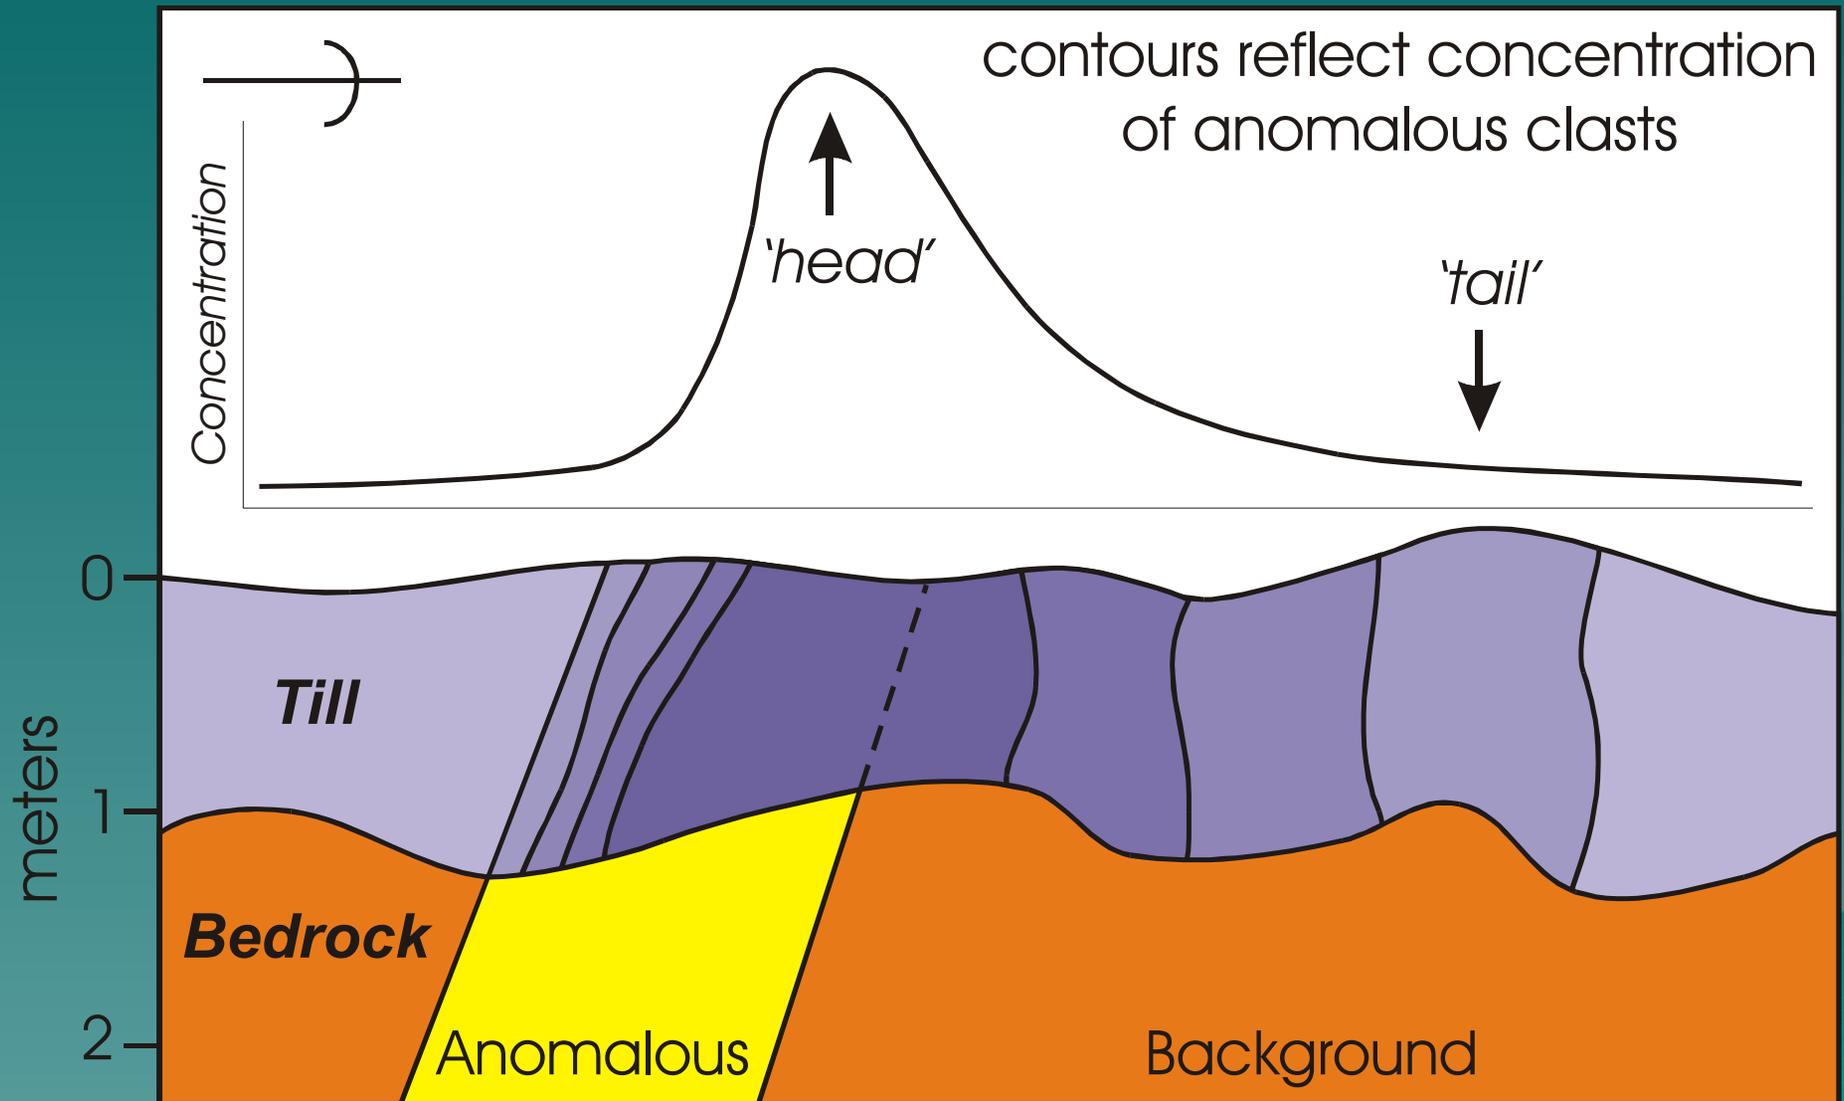

Data from Finck & Stea (1995)

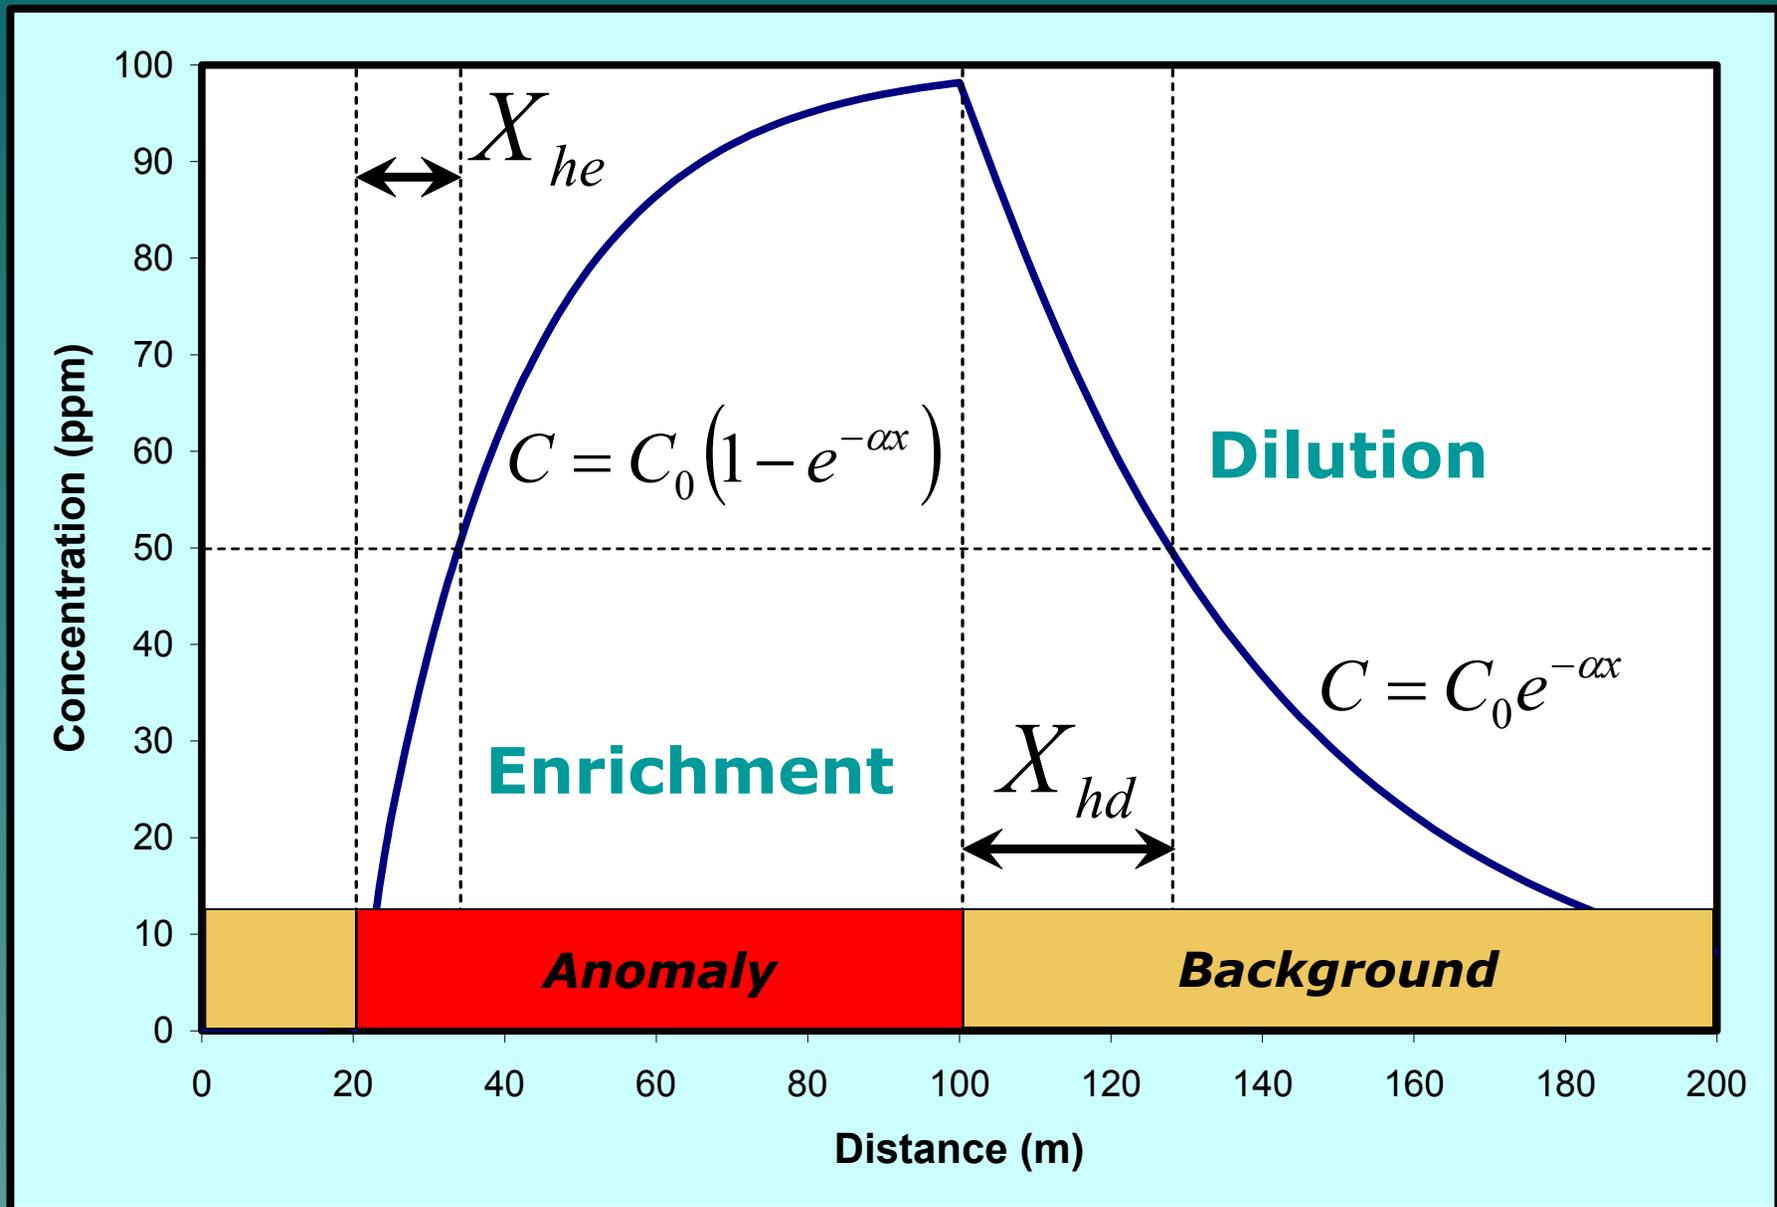

Glacial Dispersion Models

- ◆ Are these quantitative numerical models consistent with the physical processes that erode, transport and deposit till?
- ◆ If not, are there alternative numerical models that are consistent with these processes?
- ◆ Do any of these models provide insight into glacial entrainment, transport and depositional processes?

Exponential Dispersion Model

Exponential Dispersion Model – Equations

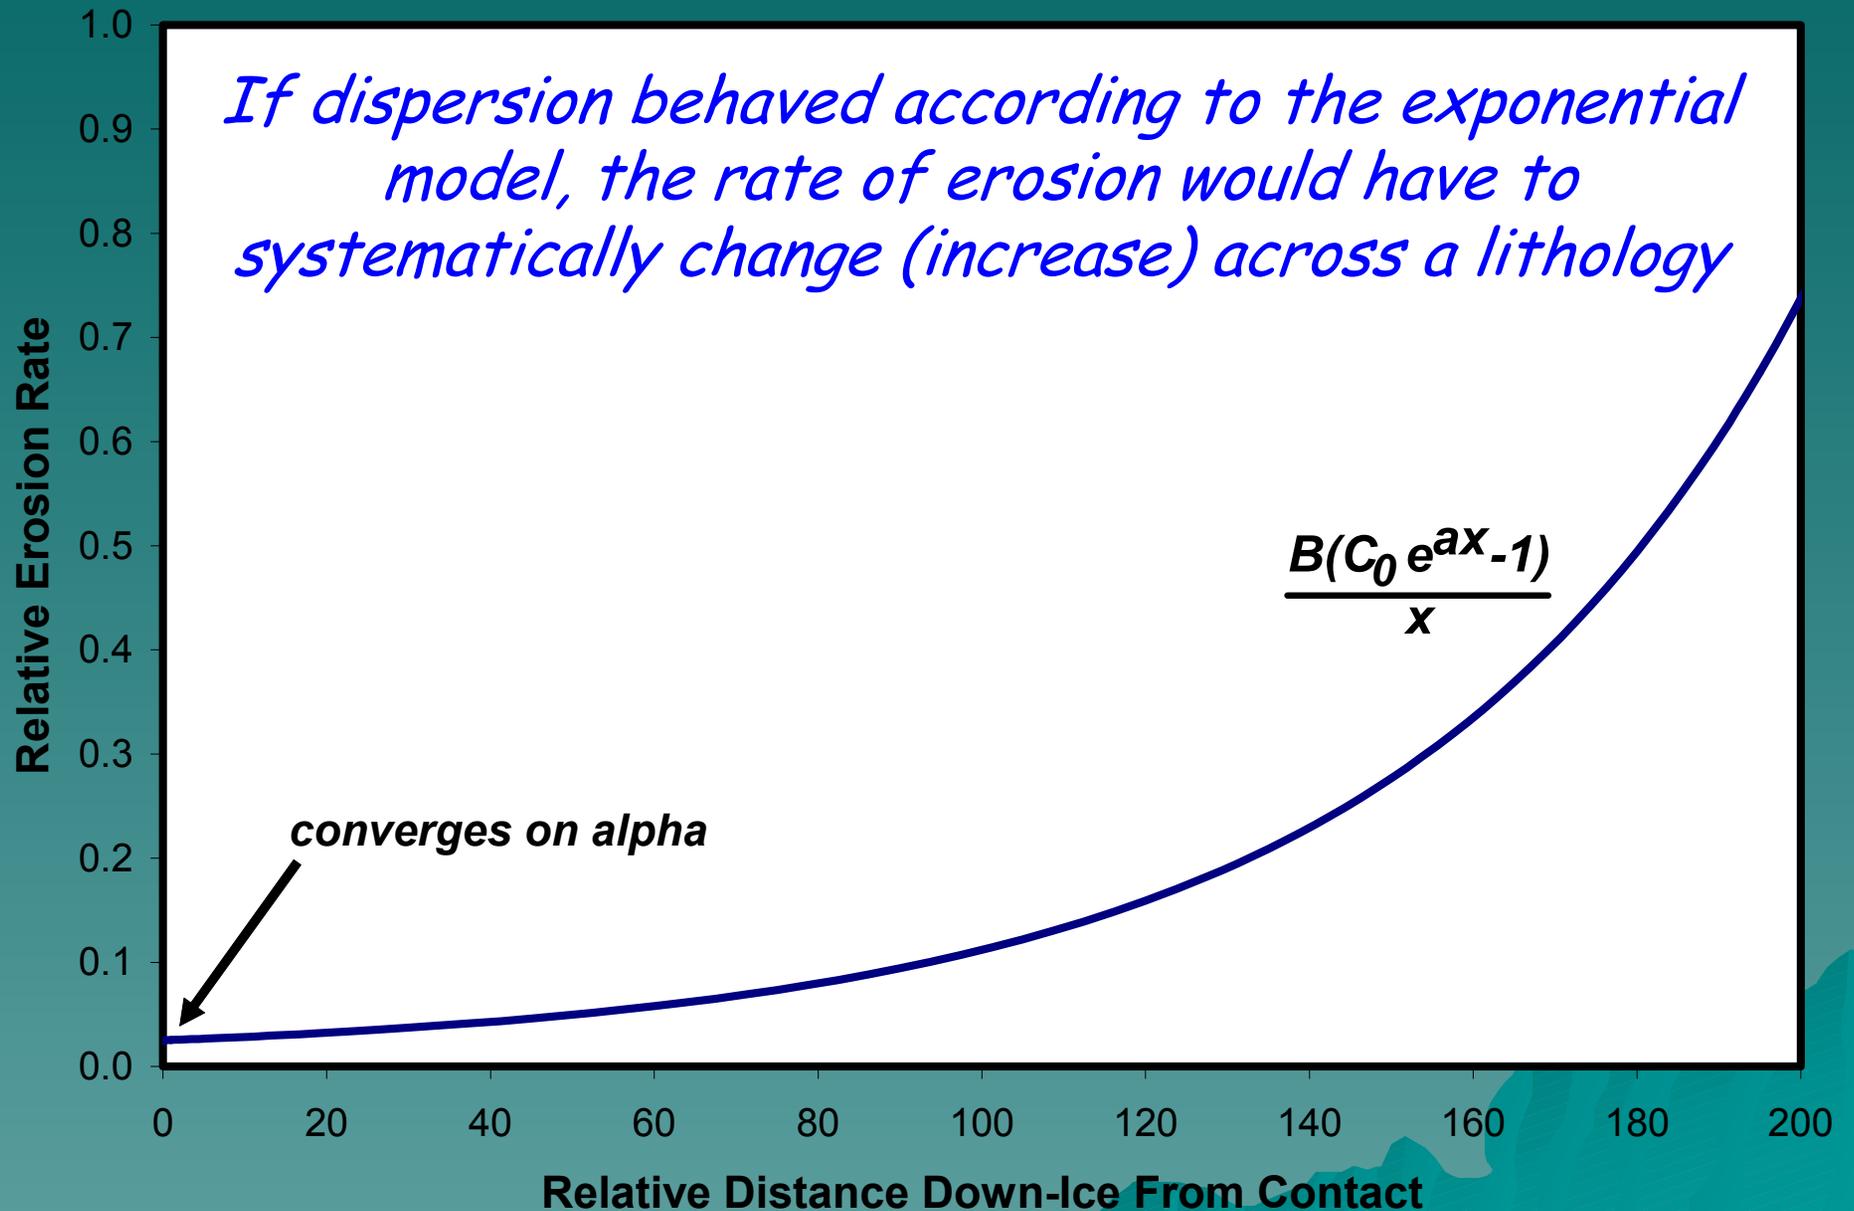

Exponential Dispersion Physical Meaning

◆ Dispersion Model:

- glacier flows from background to anomalous rocks, both of which are homogeneous
- en-glacial load first contains a certain amount of background material; anomalous material is added
- The rate of addition of the anomalous material necessary to create an exponential pattern can be determined

| | |
|---|---|
| Till of Background Composition | Till of Progressively More Anomalous Composition |
| Background Rock | Anomalous Rock |

Exponential Dispersion Physical Meaning

Exponential Dispersion Physical Meaning

◆ Dispersion Model:

- erosion rates are constant over each rock
(*although they may be different & locally variable*)
- therefore, amount of anomalous material increases linearly with distance
- over anomalous rock, the background concentration is diluted by the addition of anomalous material (**a** = amount added)
- **b** = amount of background material in glacial load before anomalous rock entrainment
- **$a/(a+b)$** = anomalous material concentration
- **$b/(a+b)$** = background material concentration

Exponential Dispersion Physical Meaning

| Rock | 0 | 1 | 2 | 3 | 4 | 5 | <i>meters</i> |
|--------------|----------|----------|----------|----------|----------|-----------|-----------------------------|
| A | 0 | 1 | 2 | 3 | 4 | 5 | <i>amounts</i> |
| B | 5 | 5 | 5 | 5 | 5 | 5 | <i>amounts</i> |
| Total | 5 | 6 | 7 | 8 | 9 | 10 | |
| % A | 0 | 17 | 28 | 37 | 45 | 50 | $a/(a+b)$ |
| % B | 100 | 83 | 72 | 63 | 55 | 50 | $b/(a+b)$ |

- ◆ Thus, this simple physical model defines an **Inverse Dispersion Model:**

$$a/(a+b) \text{ \& } b/(a+b)$$

Inverse Dispersion Model

- ◆ ***This model is different from an exponential model!***

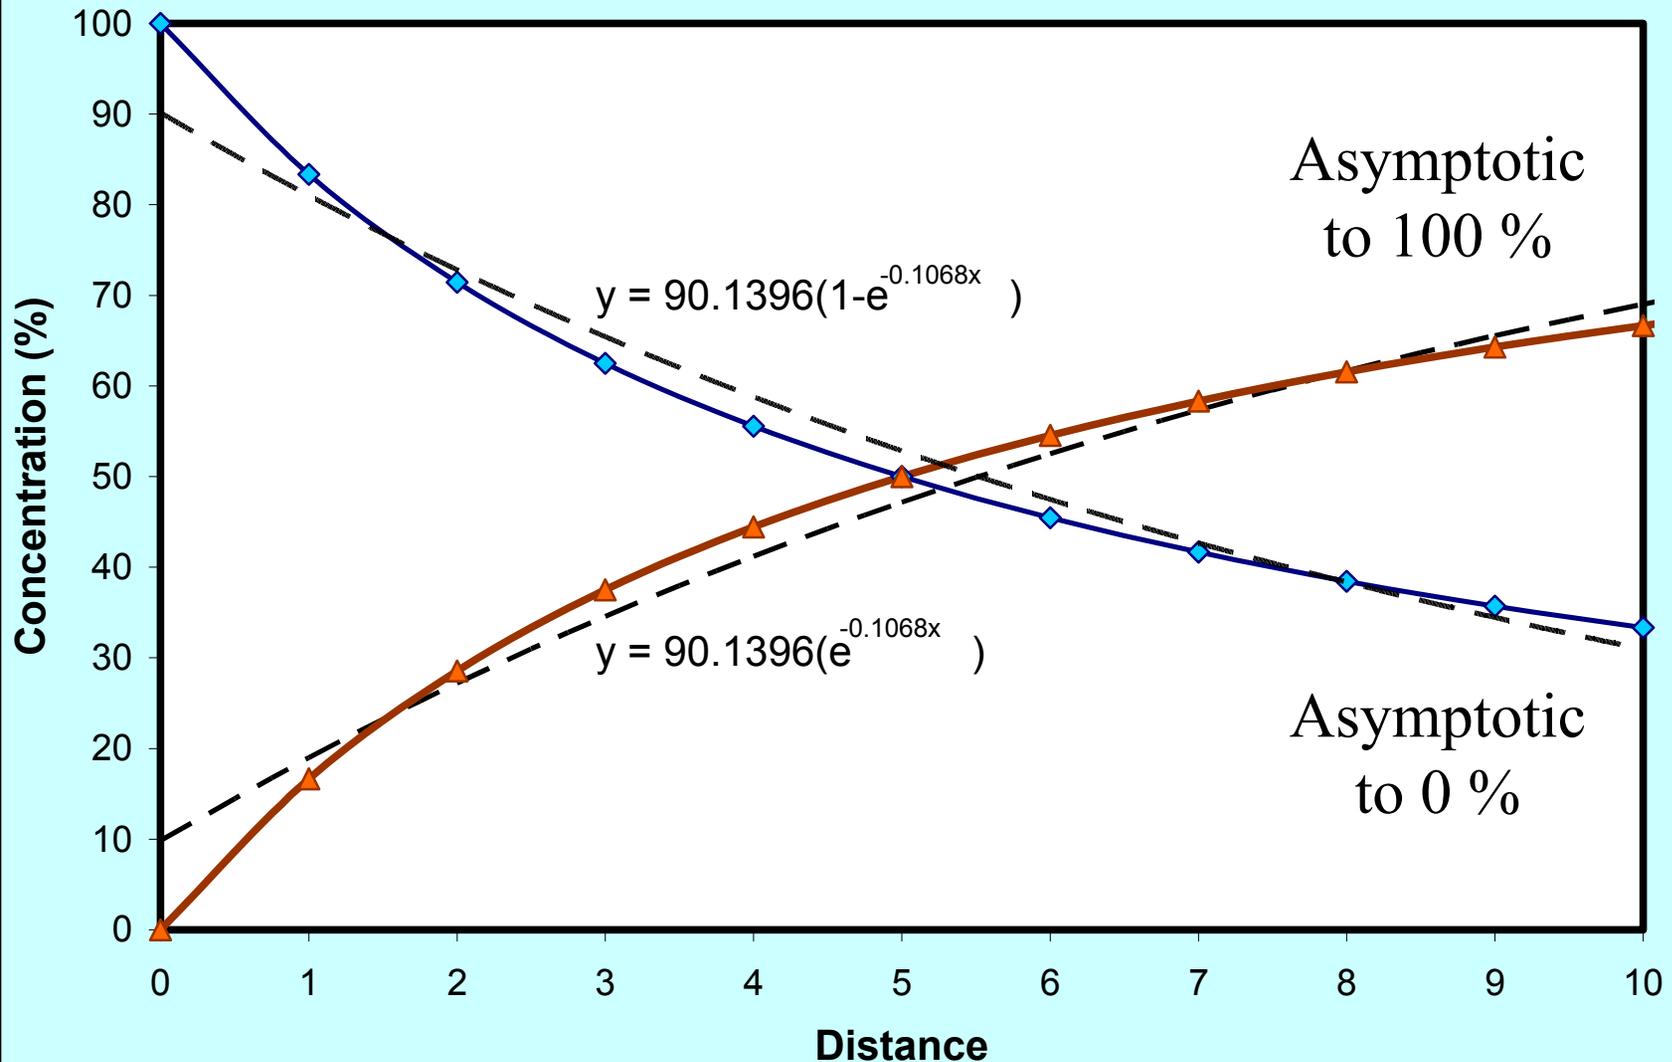

$$e^{-x} = \sum_{n=0}^{\infty} \frac{(-x)^n}{n!} = 1 - x + \frac{x^2}{2} - \frac{x^3}{6} \dots \neq \frac{c}{c+x}$$

- ◆ ***The Exponential Function:***

- initially decreases slower than the inverse function
- converges to 0 faster than the inverse function

Dispersion Physical Meaning

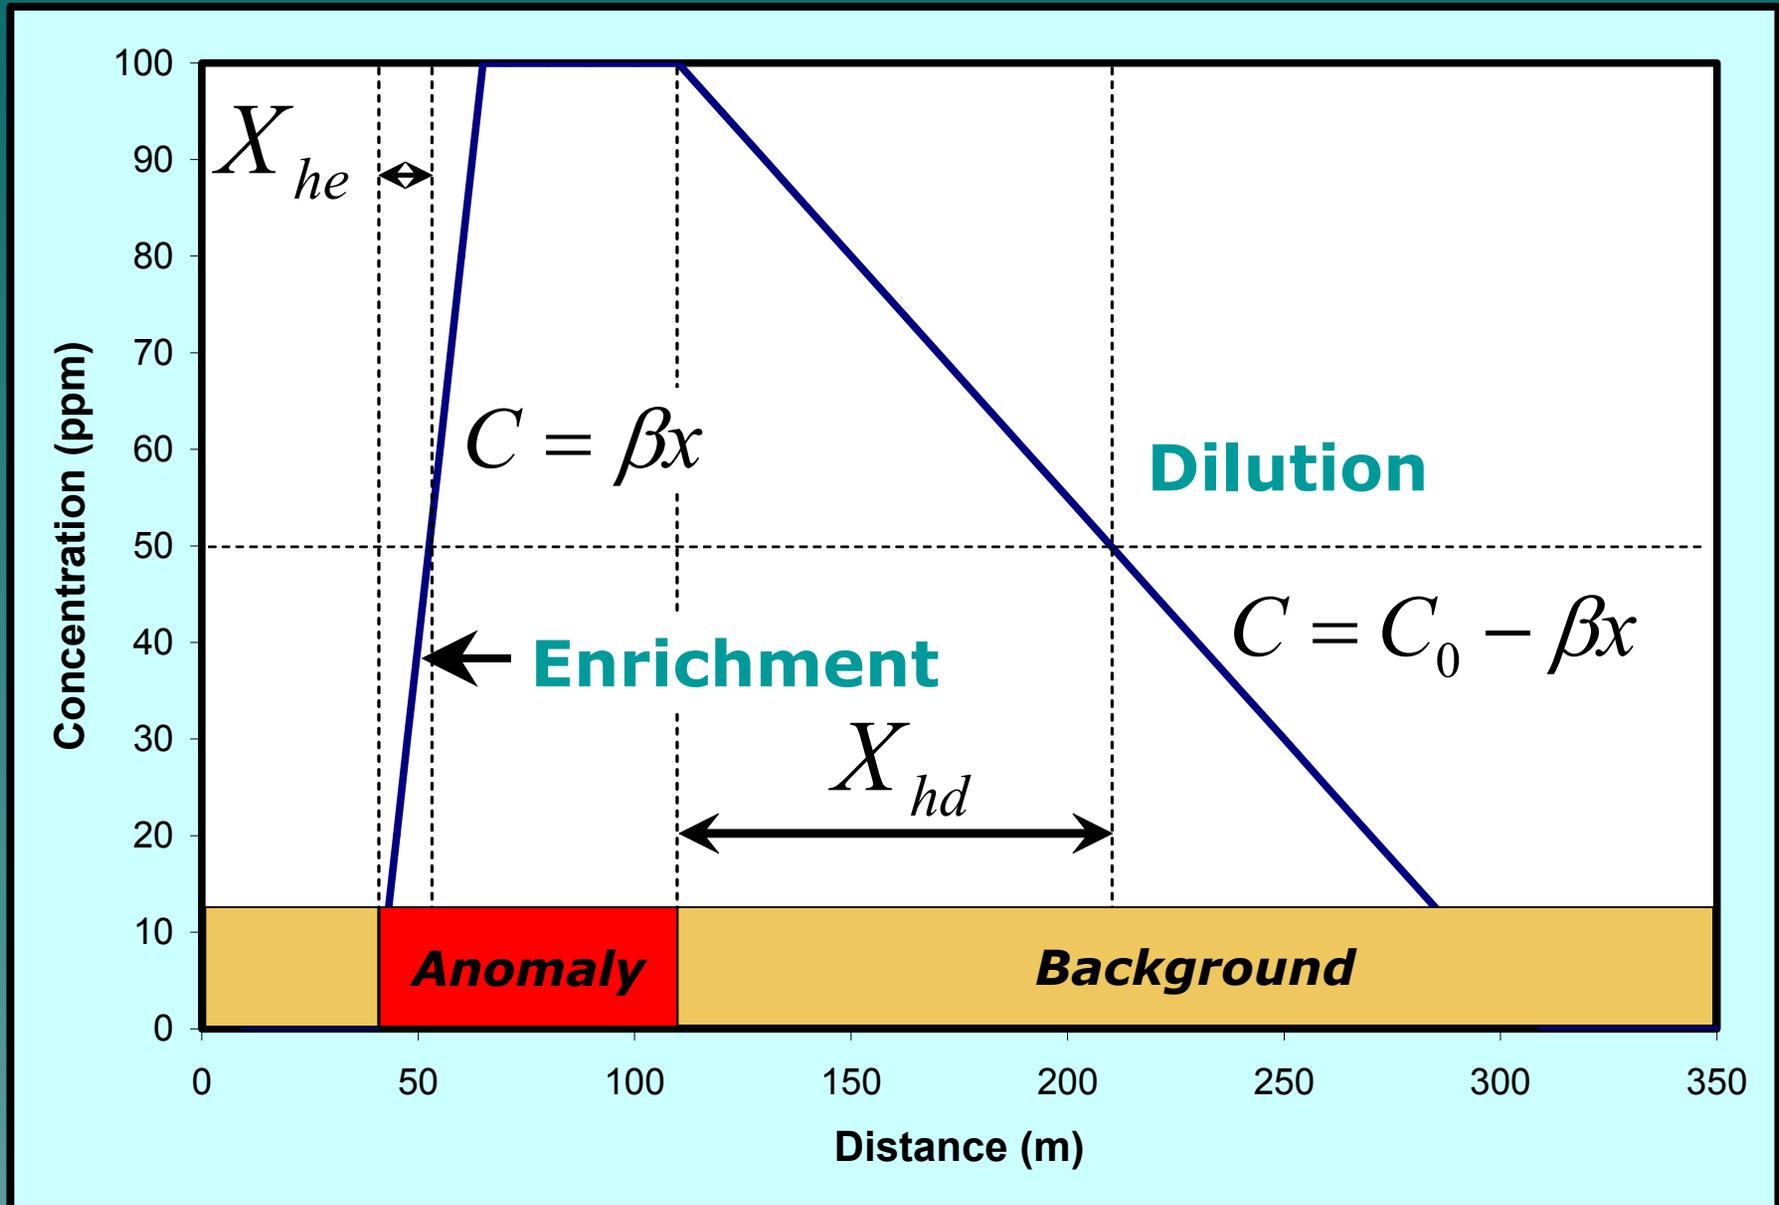

Best-fit exponential function does not 'fit' the 'inverse' model

Linear Dispersion Model

- ◆ What about the linear dispersion model?

Linear Dispersion Model – Equations

Linear Dispersion Physical Meaning

- ◆ if glacial erosion is constant, anomalous material is added to the en-glacial load **linearly** ($da = c > 0$)
- ◆ thus, the only way to produce linear dilution or enrichment patterns is to ensure the amount of material in the en-glacial load is constant ($a + b = k$)
- ◆ so, for each increment of anomalous material added, an equal amount of background material must be lost from the en-glacial load (possibly due to shearing) to locations higher in the glacier; ($da = -db$)
- ◆ This must happen in spite of the fact that the composition of the en-glacial load becomes progressively more enriched in anomalous material

Linear Dispersion Physical Meaning

| Rock | 0 | 1 | 2 | 3 | 4 | 5 | <i>meters</i> |
|--------------|------------|-----------|-----------|-----------|-----------|------------|-------------------|
| A | 0 | 1 | 2 | 3 | 4 | 5 | <i>amounts</i> |
| B | 5 | 4 | 3 | 2 | 1 | 0 | <i>amounts</i> |
| Total | 5 | 5 | 5 | 5 | 5 | 5 | |
| % A | <i>0</i> | <i>20</i> | <i>40</i> | <i>60</i> | <i>80</i> | <i>100</i> | <i>a/k</i> |
| % B | <i>100</i> | <i>80</i> | <i>60</i> | <i>40</i> | <i>20</i> | <i>0</i> | <i>b/k</i> |

- ◆ ***a/k*** & ***b/k*** are linear decay sequences
- ◆ To create a linear decay, only background material can be removed from the en-glacial load; unfortunately, this load becomes progressively more enriched in anomalous material

Improbable!

Dispersion Models

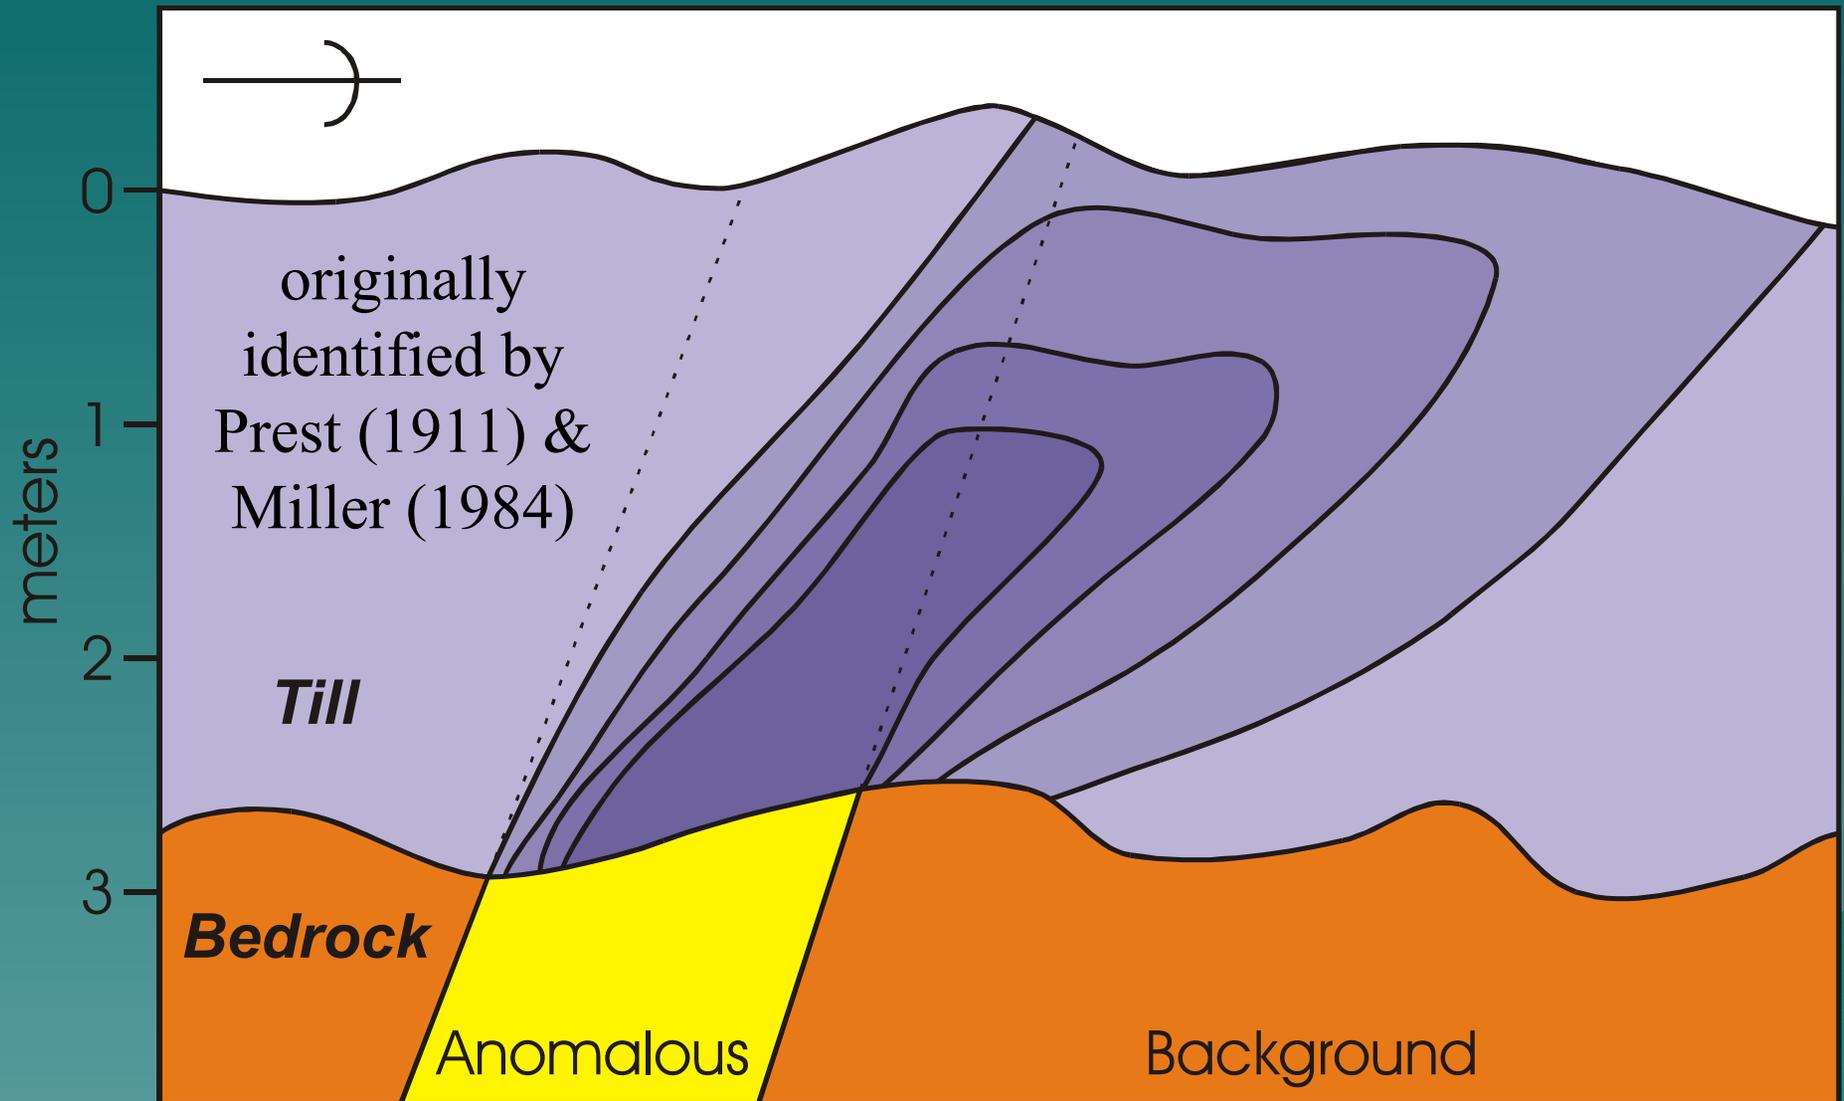

Both dispersion models are
***physically inconsistent with
sub-glacial processes!***

- ◆ Does an alternative dispersion model exist that explains the observed dilution / enrichment patterns in glacial till?

YES !

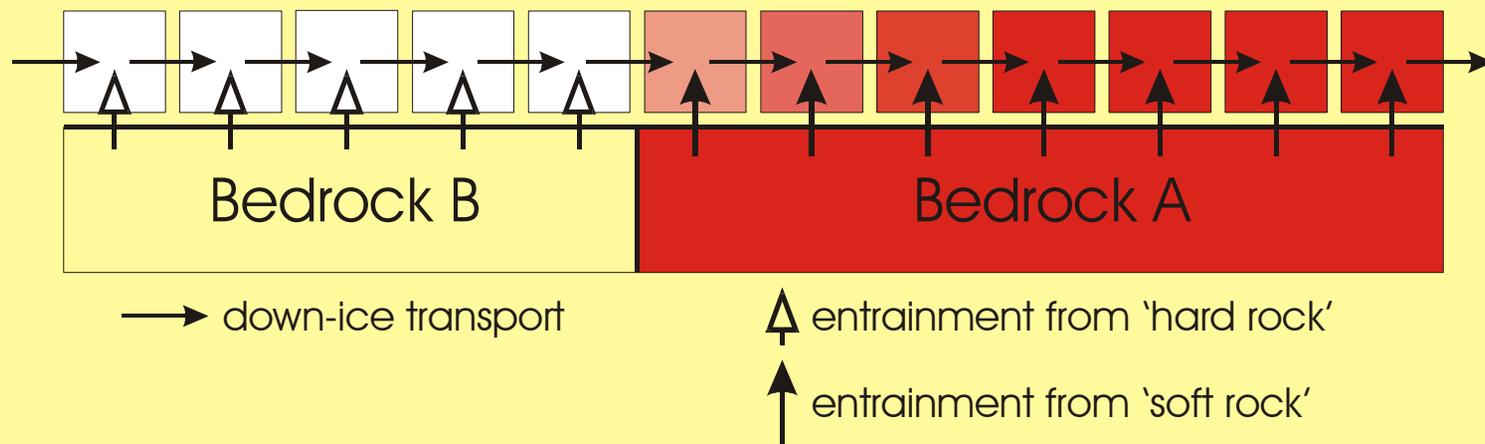

Aggradational Dispersion Model

Aggradational Dispersion Model

Glacial Flow Direction \longrightarrow

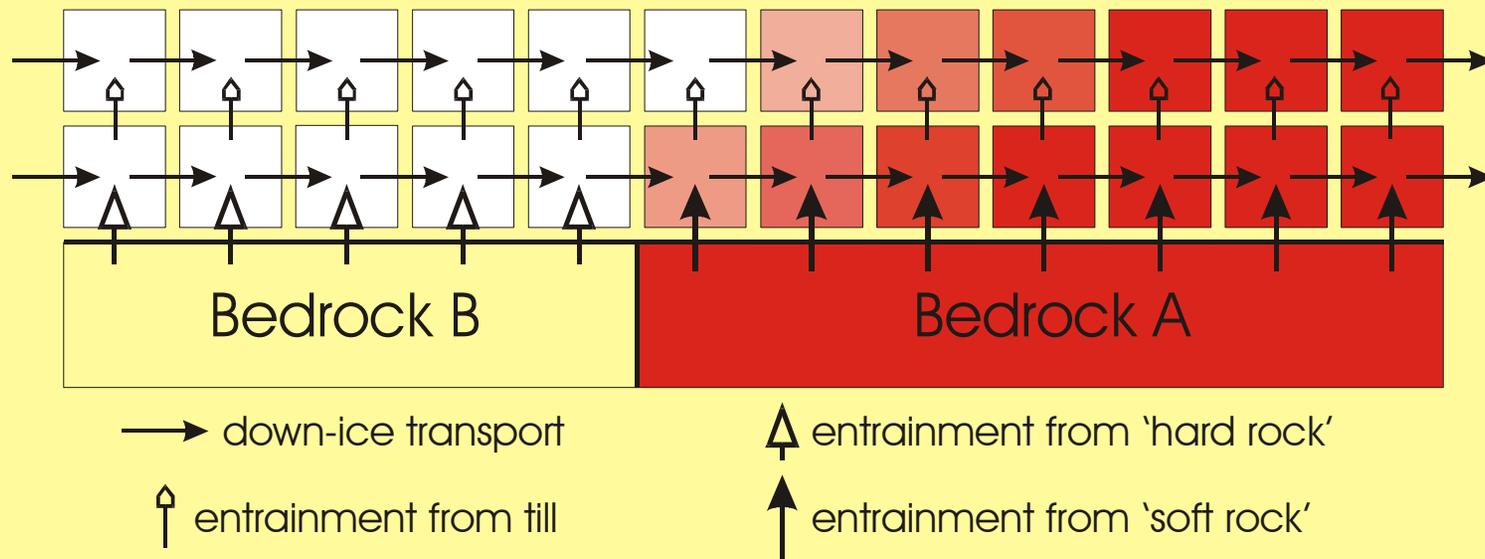

- in the basal layer, the bedrock compositional contact is sharp, so the till immediately above it exhibits an inverse decay / enrichment pattern

Aggradational Dispersion Model

Glacial Flow Direction →

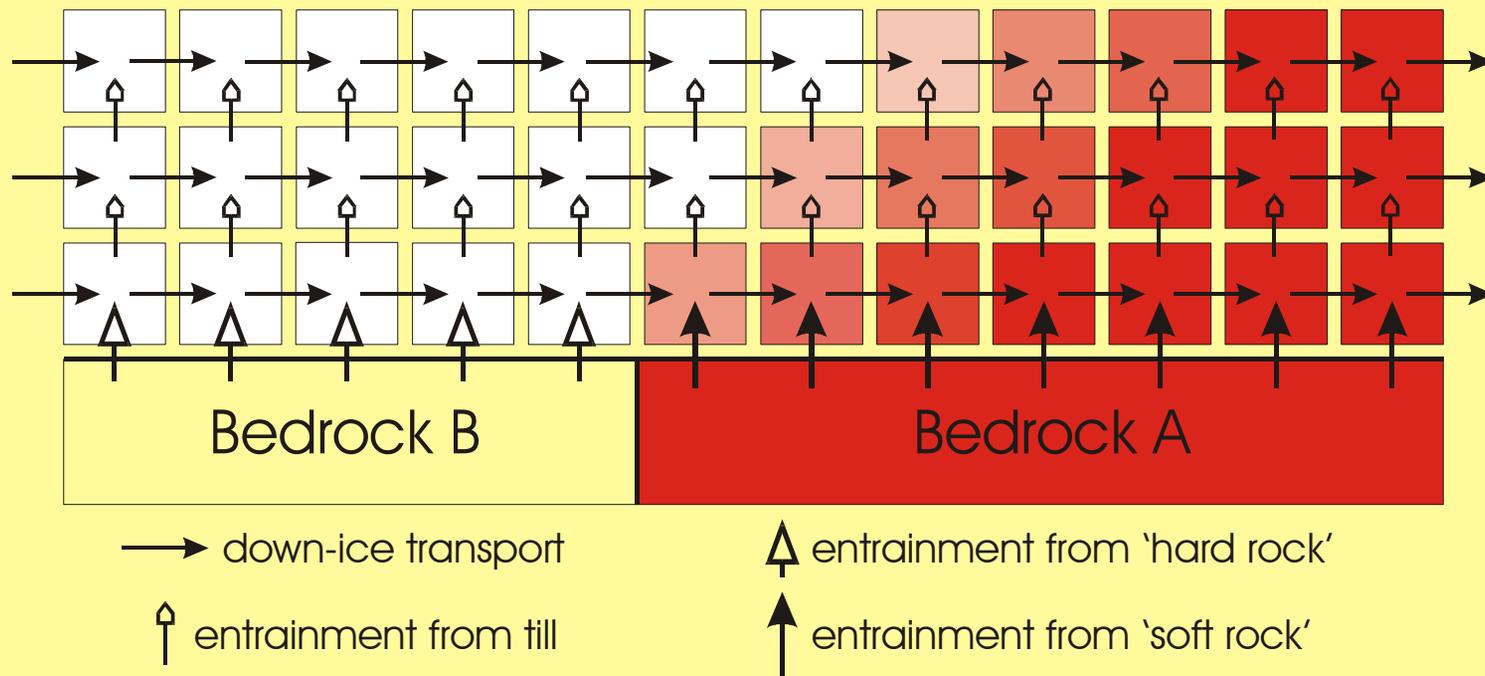

- the anomalous material in the first layer of ice is mixed with background material, then transported up- and down-ice
- the compositional contact in the second till layer is thus more gradational

Aggradational Dispersion Model

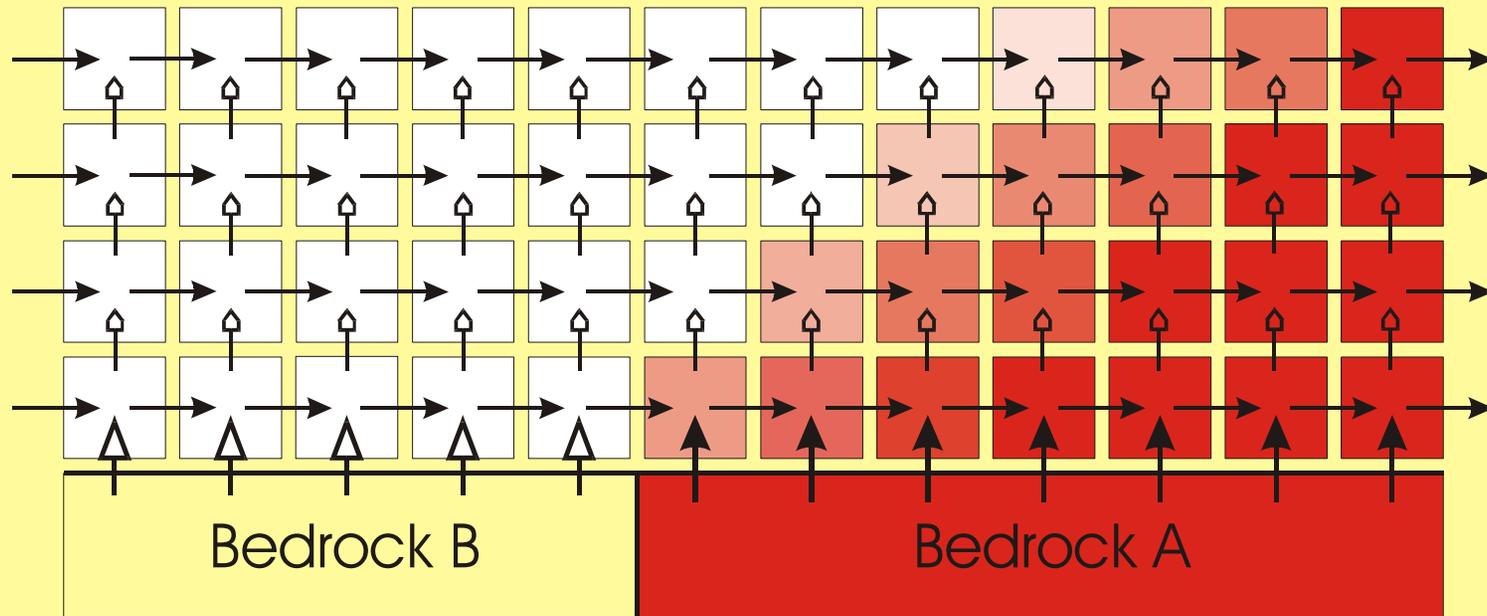

Glacial Flow Direction →

- the third till layer exhibits even more of a gradational compositional 'contact' (*non-inverse dispersion model*)

Aggradational Dispersion Model

Glacial Flow Direction →

→ down-ice transport

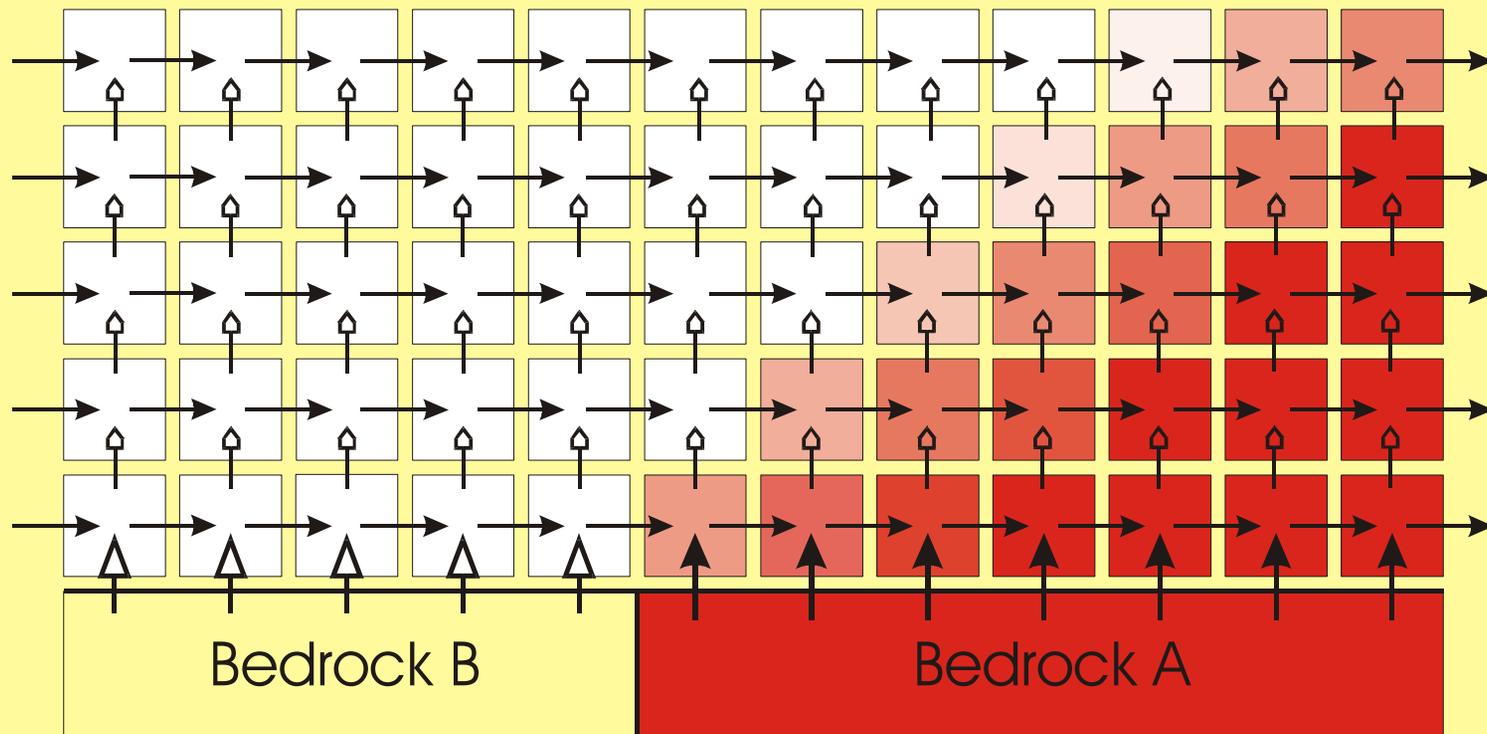

↑ entrainment from till

△ entrainment from 'hard rock'

↑ entrainment from 'soft rock'

Aggradational Dispersion Model

Glacial Flow Direction →

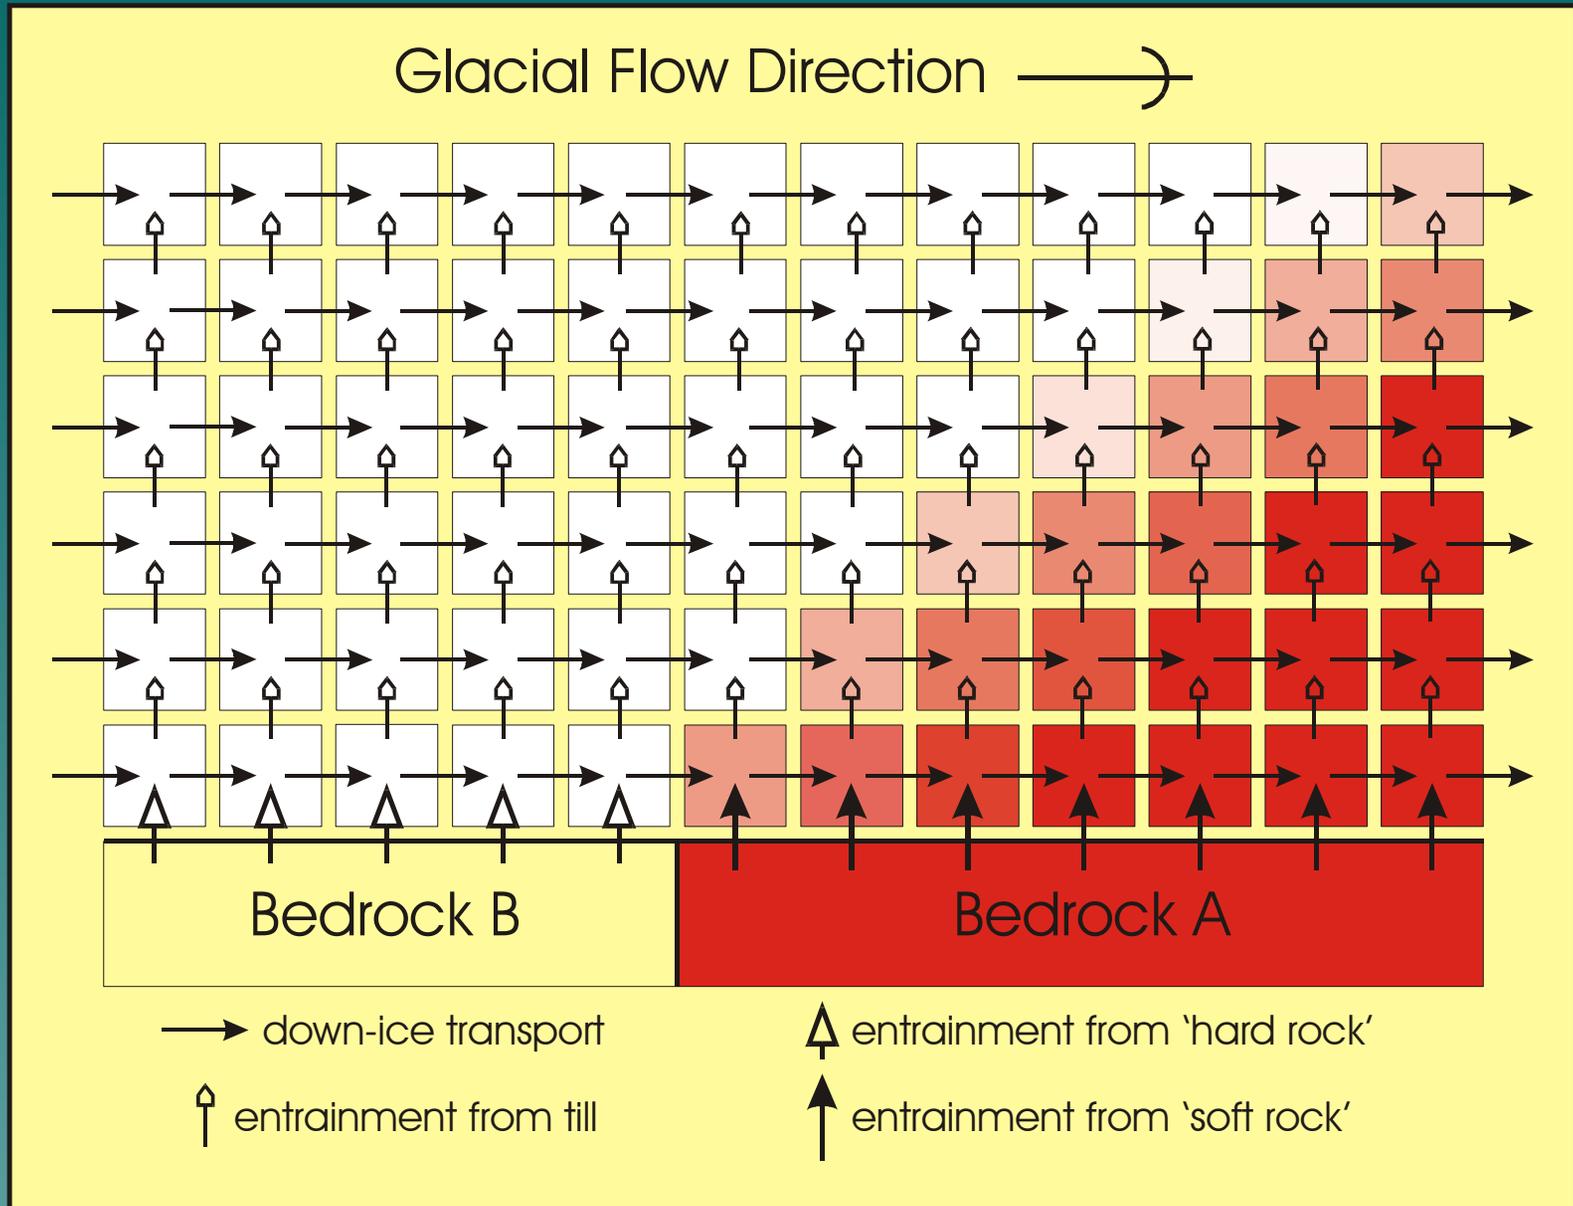

→ down-ice transport

↑ entrainment from till

△ entrainment from 'hard rock'

↑ entrainment from 'soft rock'

Background

Anomaly

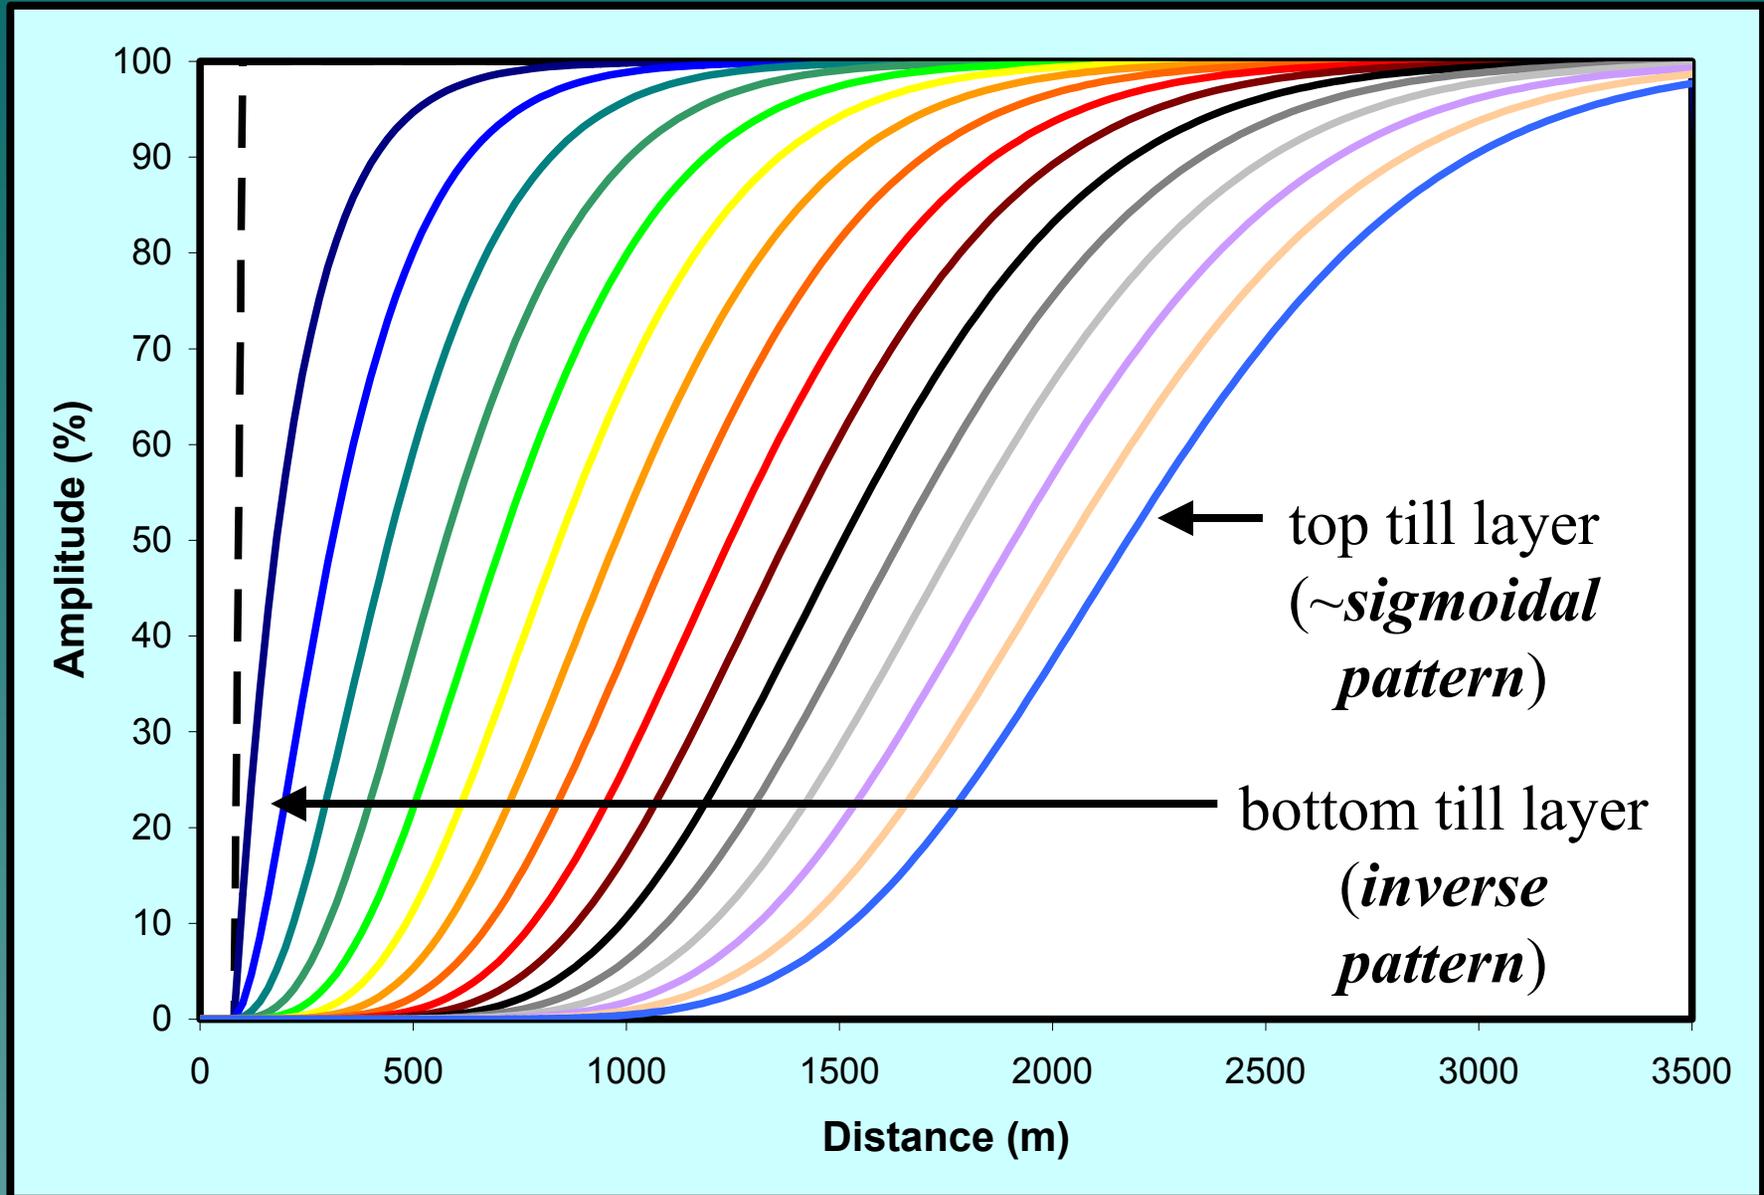

Background

- anomalous material is smeared down-ice
- width of the anomaly increases down-ice
- concentrations of most anomalous material decrease down-ice (diluted by mixing)
- concentration patterns differ in each layer of the till

Background Material Dispersion Patterns

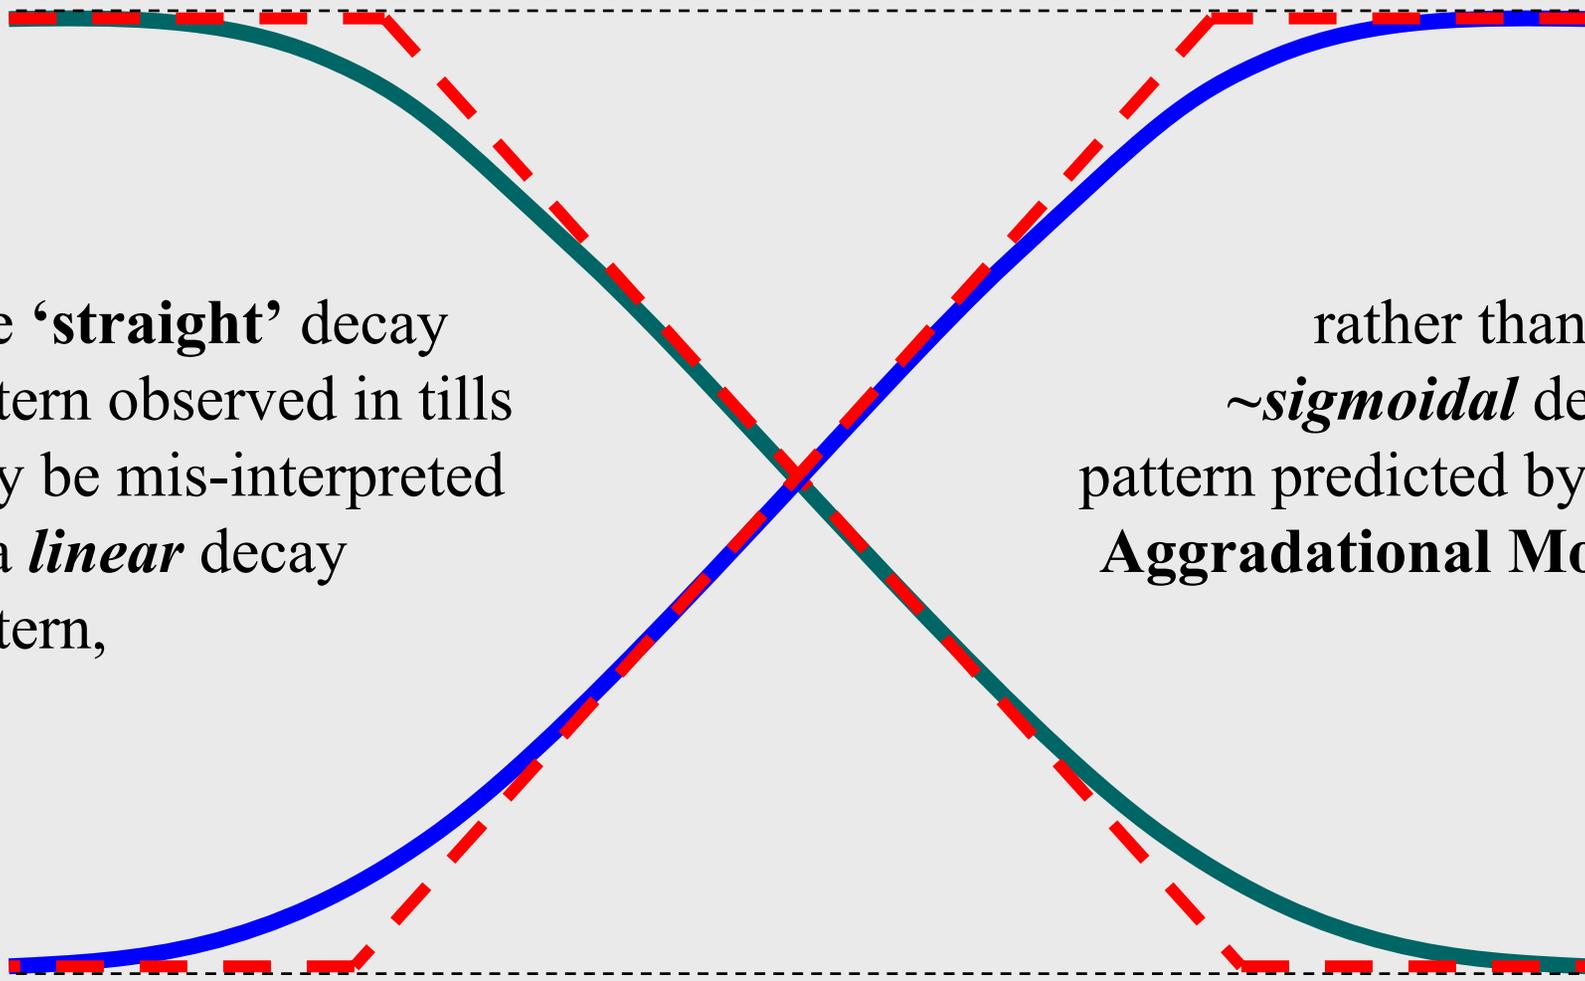

Anomalous Material Dispersion Patterns

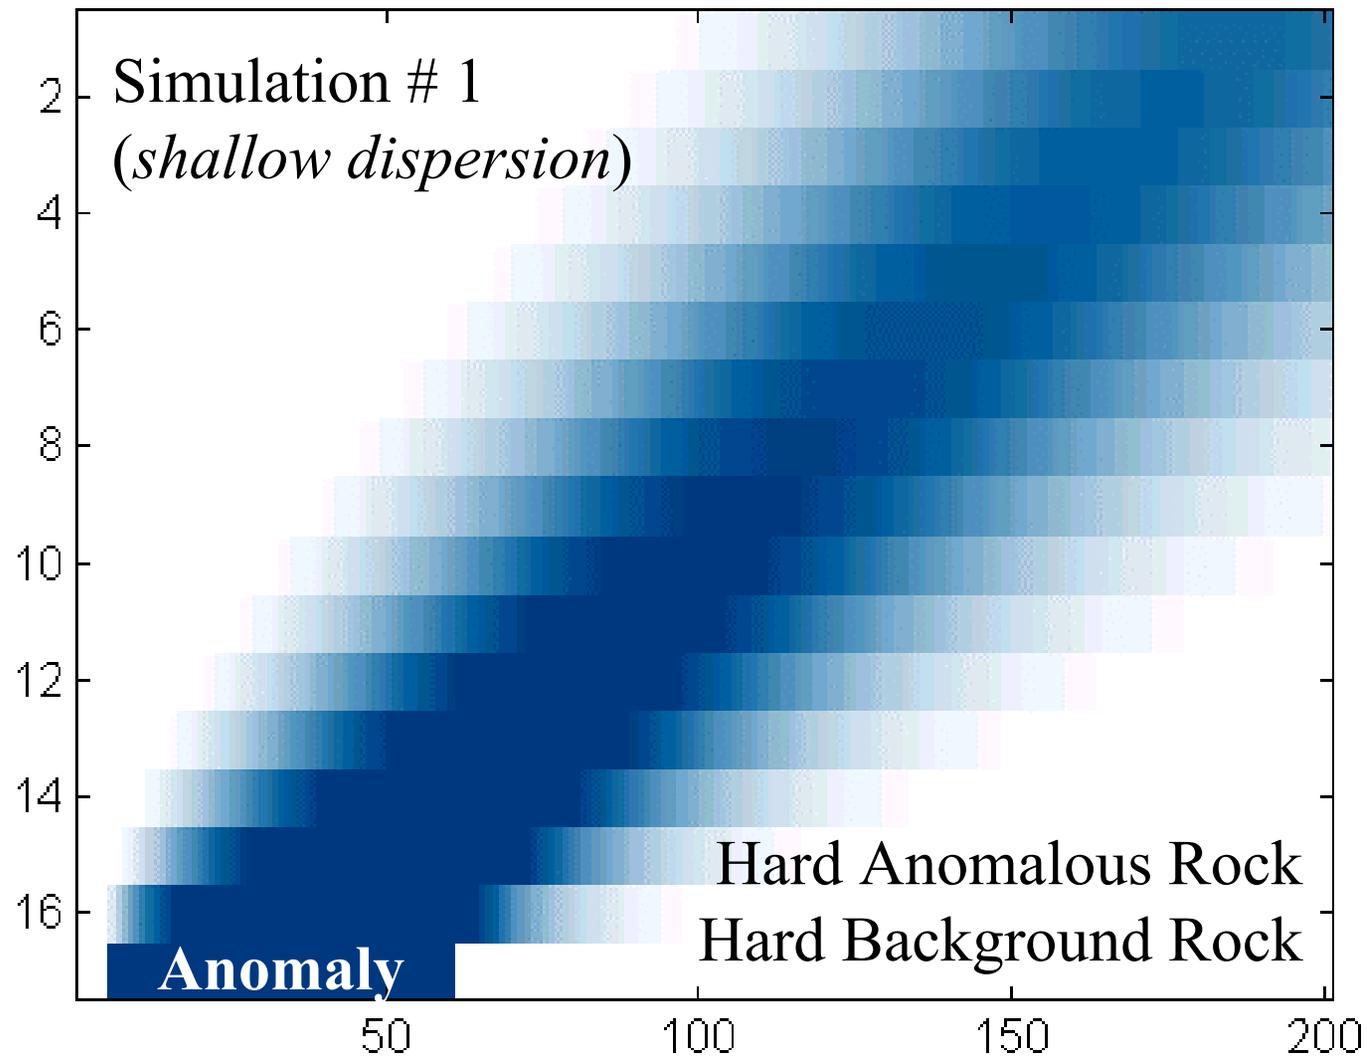

Aggradational Dispersion Model

The 'straight' decay pattern observed in tills may be mis-interpreted as a *linear* decay pattern,

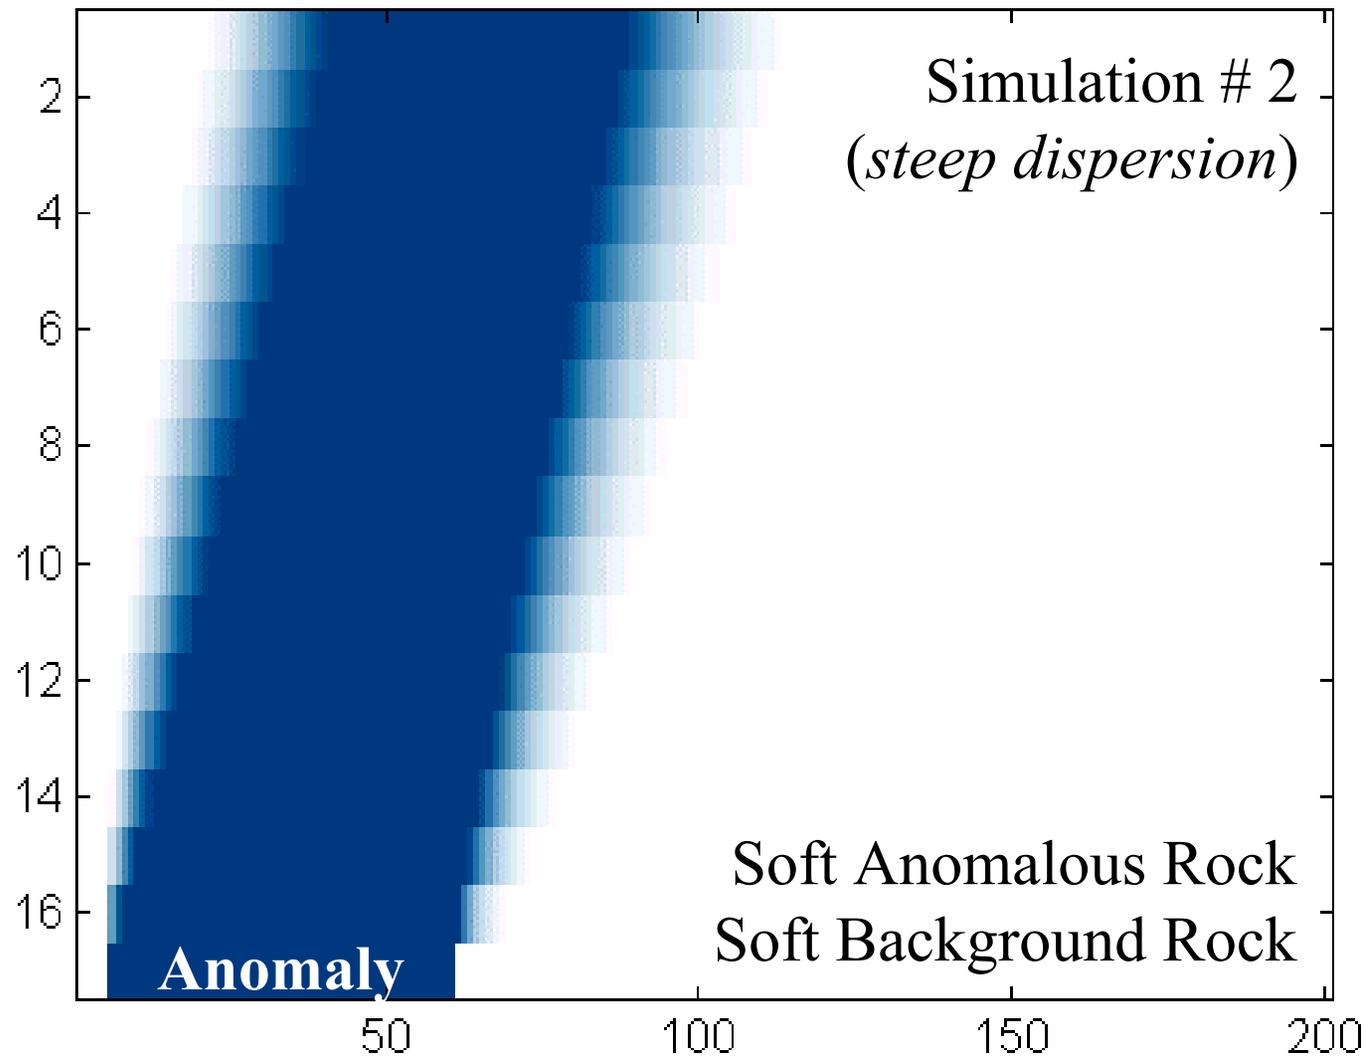

rather than the *~sigmoidal* decay pattern predicted by the **Aggradational Model**

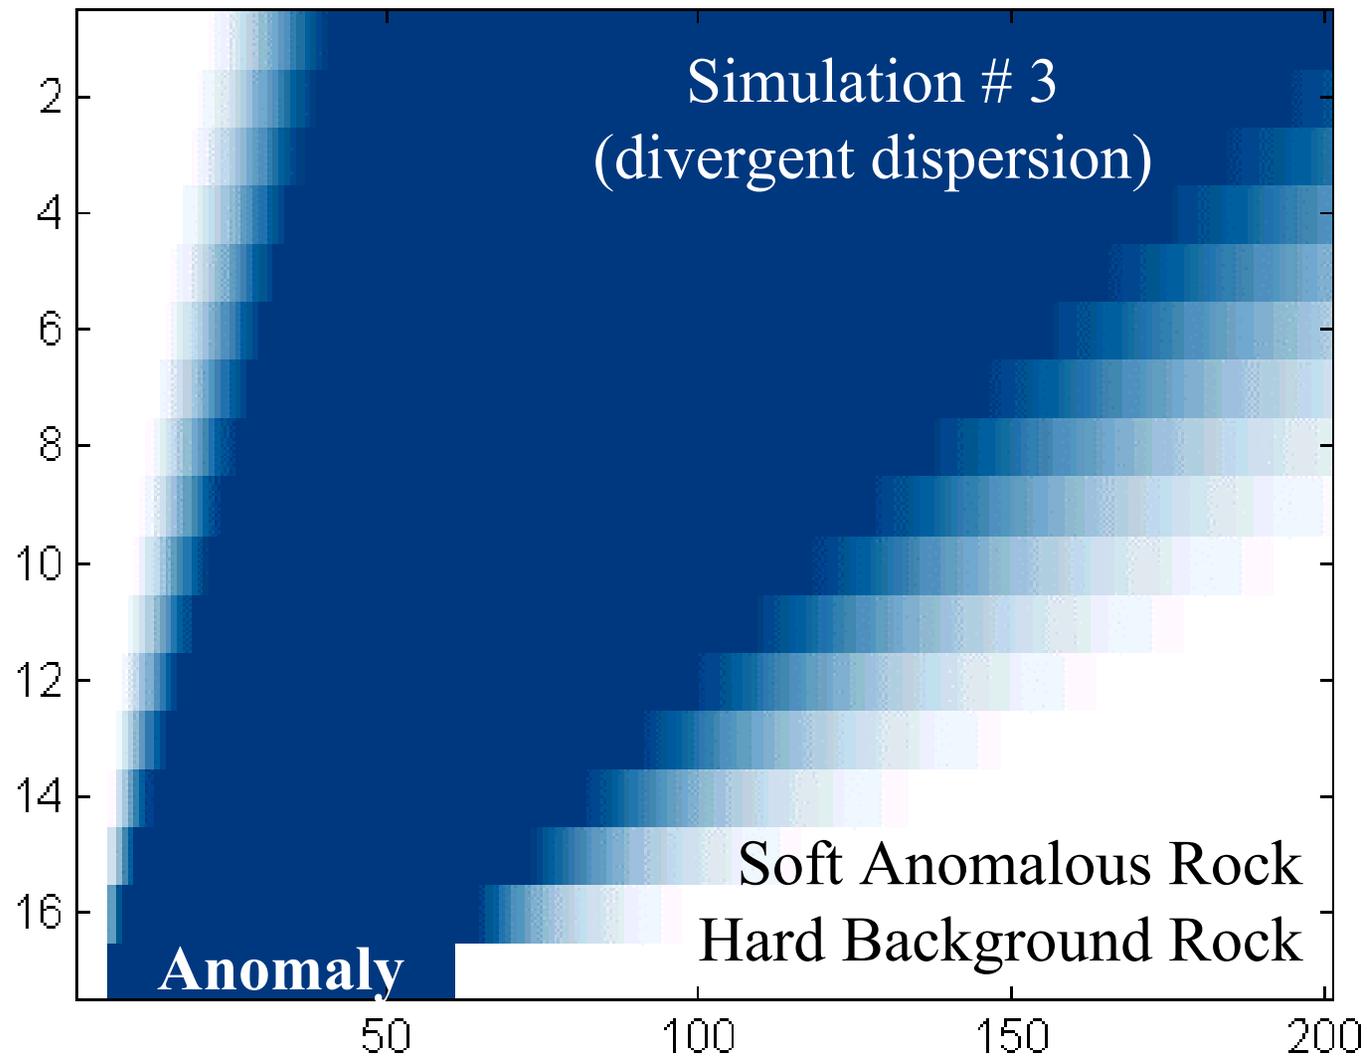

Aggradational Dispersion Model

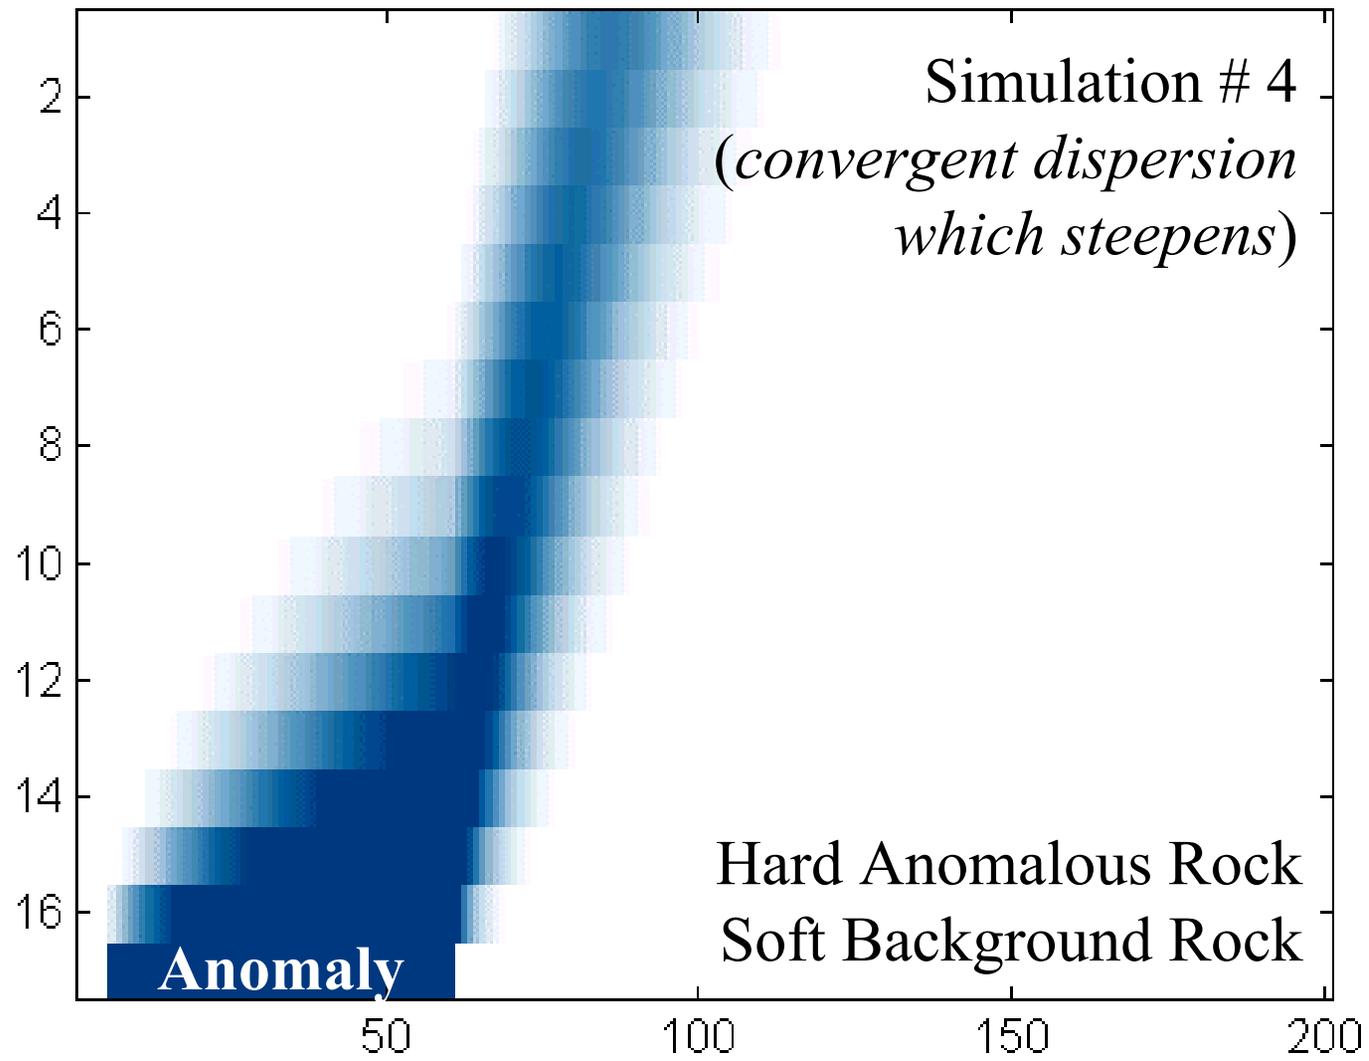

Aggradational Dispersion Model

Aggradational Dispersion Model

Aggradational Dispersion Model

Conclusions

- ◆ The ***Exponential and Linear Dispersion Models*** are numerically inconsistent with the physical model for which they are ascribed
- ◆ An alternative ***Aggradational Dispersion Model*** is proposed that has both physical justification and explains both observed dispersion patterns (*'pseudo-exponential'* and *'pseudo-linear'*)

Conclusions

- ◆ The type of dispersion pattern created by the ***Aggradational Dispersion Model*** depends on the level that one looks in the till
- ◆ Mineralogical and geochemical sampling:
 - at deep levels in thicker till sections, or in thin tills (*lodgement tills*) will produce 'inverse' dispersion patterns
 - at shallow levels in thicker till sections (*ablation tills*) will produce '~sigmoidal' dispersion patterns

Conclusions

- ◆ The ***Aggradational Dispersion Model*** provides insight into how glacial dispersion patterns can be controlled by the '*erodability*' of the bedrock
 - hard rock => shallower dispersion
 - soft rock => steeper dispersion
 - soft anomaly => divergent dispersion
 - hard anomaly => convergent dispersion steepens

Future Work

- ◆ To date, the **Aggradational Dispersion Model** has been represented by a finite difference/material transfer model
- ◆ Need to develop a quantitative representation of the **Aggradational Dispersion Model** by solving this partial differential equation

$$\left(\frac{\partial a}{\partial x}\right) + \left(\frac{\tau}{T}\right)\left(\frac{\partial a}{\partial z}\right) = k\nabla^2(a) = k\left(\frac{\partial^2 a}{\partial x^2} + \frac{\partial^2 a}{\partial z^2}\right)$$

- ◆ This will produce an equation describing the family of curves which can be regressed to estimate the location of an up-ice contact

Thank You!
